

# Validatetools

Edwin de Jonge, Statistics Netherlands

@edwindjonge | [github.com/edwindj](https://github.com/edwindj)

# Who am I?

- ▶ Data scientist / Methodologist at Statistics Netherlands (aka CBS).
- ▶ Author of several R-packages, including `whisker`, `validate`, `errorlocate`, `docopt`, `tableplot`, `chunked`, `ffbase`,...
- ▶ Co-author of *Statistical Data Cleaning with applications in R (2018)* (sorry for the plug, but relevant for this talk...)

# CAUTION: BAD DATA

**BAD DATA QUALITY  
MAY RESULT IN  
FRUSTRATION AND  
LEAD TO DROP  
KICKING YOUR  
COMPUTER**

## Data cleaning...

A large part of your and our job is spent in data-cleaning:

- ▶ getting your data in the right shape (e.g. tidyverse, recipes)
- ▶ checking validity (e.g. validate, dataMaid, errorlocate)
- ▶ impute values for missing or erroneous data (e.g. VIM, simputation, recipes)
- ▶ see data changes, improvements (e.g. daff, diffobj, lumberjack)

### Desirable data cleaning properties:

- ▶ Reproducible data checks.
- ▶ Automate repetitive data checking (e.g. monthly/quarterly).
- ▶ Monitor data improvements / changes.
- ▶ **How** do this systematically?

**RULES**

# Data Cleaning philosophy

- ▶ **“Explicit is better than implicit”.**
- ▶ Data rules are solidified **domain knowledge**.
- ▶ Store these as **validation rules** and apply these when necessary.

## Advantages:

- ▶ Easy checking of rules: data validation.
- ▶ Data quality statistics: how often is each rule violated?
- ▶ Allows for reasoning on rules: which variables are involved in errors? How do errors affect the resulting statistic?
- ▶ Simplifies rule changes and additions.

## R package validate

With package `validate` you can formulate explicit rules that data must conform to:

```
library(validate)
check_that( data.frame(age=160, job = "no", income = 3000)
  age >= 0,
  age < 150,
  job %in% c("yes", "no"),
  if (job == "yes") age >= 16,
  if (income > 0) job == "yes"
)
```

## Rules (2)

A lot of datacleaning packages are using validate rules to facilitate their work.

- ▶ validate: validation **checks** and data **quality stats** on data.
- ▶ errorlocate: to find **errors** in variables (in stead of records)
- ▶ rspa: data **correction** under data constraints
- ▶ deductive: deductive **correction**
- ▶ dcmodify: deterministic **correction** and **imputation**.

## Why-o-why validate tools?

- ▶ We have package validate, what is the need?

Because we'd like to...

- ▶ clean up rule sets ( kind of meta-cleaning... ).
- ▶ detect and resolve problems with rules:
  - Detect **conflicting** rules.
  - Remove **redundant** rules.
  - **Substitute** values and **simplify** rules.
  - Detect unintended rule **interactions**.
- ▶ check the rule set using formal logic (without any data!).
- ▶ solve these kind of fun problems :-)

# Problem: infeasibility

## Problem

One or more rules in conflict: all data incorrect! (*and yes that happens when rule sets are large ...*)

```
library(validatetools)
rules <- validator( is_adult = age >=21
                   , is_child = age < 18
                   )
is_infeasible(rules)
```

```
## [1] TRUE
```

**KEEP CALM**

**AND**

**RESOLVE  
CONFLICT**

## Conflict, and now?

```
rules <- validator( is_adult = age >=21
                   , is_child = age < 18
                   )
# Find out which rule would remove the conflict
detect_infeasible_rules(rules)
```

```
## [1] "is_adult"
```

```
# And its conflicting rule(s)
is_contradicted_by(rules, "is_adult")
```

```
## [1] "is_child"
```

- ▶ One of these rules needs to be removed
- ▶ Which one? Depends on human assessment. . .

## Detecting and removing redundant rules

Rule  $r_1$  may imply  $r_2$ , so  $r_2$  can be removed.

```
rules <- validator( r1 = age >= 18  
                   , r2 = age >= 12  
                   )  
detect_redundancy(rules)
```

```
##      r1      r2  
## FALSE  TRUE
```

```
remove_redundancy(rules)
```

```
## Object of class 'validator' with 1 elements:  
##      r1: age >= 18
```

## Value substitution

```
rules <- validator( r1 = if (gender == "male") weight > 50
                   , r2 = gender %in% c("male", "female")
                   )

substitute_values(rules, gender = "male")
```

```
## Object of class 'validator' with 2 elements:
##  r1           : weight > 50
##  .const_gender: gender == "male"
```

## Conditional statement

A bit more complex reasoning, but still classical logic:

```
rules <- validator( r1 = if (income > 0) age >= 16
                   , r2 = age < 12
                   )
# age > 16 is always FALSE so r1 can be simplified
simplify_conditional(rules)
```

```
## Object of class 'validator' with 2 elements:
##  r1: income <= 0
##  r2: age < 12
```

## All together now!

`simplify_rules` applies all simplification methods to the rule set

```
rules <- validator( r1 = job %in% c("yes", "no")
                   , r2 = if (job == "yes") income > 0
                   , r3 = if (age < 16) income == 0
                   )
simplify_rules(rules, job = "yes")
```

```
## Object of class 'validator' with 3 elements:
##  r2          : income > 0
##  r3          : age >= 16
##  .const_job: job == "yes"
```

# How does it work?

validatetools:

- ▶ reformulates rules into formal logic form.
- ▶ translates them into a mixed integer program for each of the problems.

## Rule types

- ▶ *linear* restrictions
- ▶ *categorical* restrictions
- ▶ *if* statements with linear and categorical restrictions

If statement is Modus ponens:

$$\begin{aligned} & \text{if } P \text{ then } Q \\ \Leftrightarrow & P \implies Q \\ \Leftrightarrow & \neg P \vee Q \end{aligned}$$

## Example

```
rules <- validator(  
  example = if (job == "yes") income > 0  
)
```

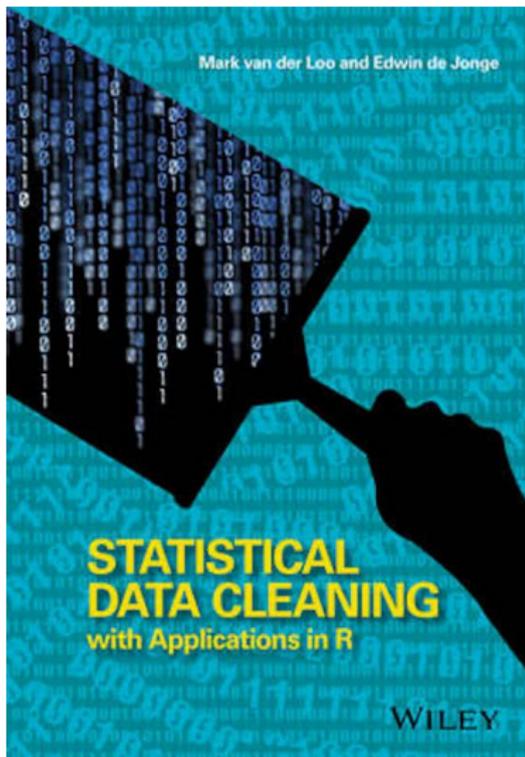

$$r_{\text{example}}(x) = \text{job} \notin \text{"yes"} \vee \text{income} > 0$$

```
print(rules)
```

```
## Object of class 'validator' with 1 elements:  
##  example: !(job == "yes") | (income > 0)
```

# Addendum

# Formal logic

## Rule set $S$

A validation rule set  $S$  is a conjunction of rules  $r_i$ , which applied on record  $\mathbf{x}$  returns TRUE (valid) or FALSE (invalid)

$$S(\mathbf{x}) = r_1(\mathbf{x}) \wedge \cdots \wedge r_n(\mathbf{x})$$

## Note

- ▶ a record has to comply to each rule  $r_i$ .
- ▶ it is thinkable that two or more  $r_i$  are in conflict, making each record invalid.

## Formal logic (2)

### Rule $r_i(x)$

A rule a disjunction of atomic clauses:

$$r_i(x) = \bigvee_j C_i^j(x)$$

with:

$$C_i^j(x) = \begin{cases} \mathbf{a}^T \mathbf{x} \leq b \\ \mathbf{a}^T \mathbf{x} = b \\ x_j \in F_{ij} \text{ with } F_{ij} \subseteq D_j \\ x_j \notin F_{ij} \text{ with } F_{ij} \subseteq D_j \end{cases}$$

# Mixed Integer Programming

Each rule set problem can be translated into a mip problem, which can be readily solved using a mip solver.

validatetools uses lpSolveApi.

$$\begin{aligned} \text{Minimize } f(\mathbf{x}) &= 0; \\ \text{s.t. } \mathbf{R}\mathbf{x} &\leq \mathbf{d} \end{aligned}$$

with  $\mathbf{R}$  and  $\mathbf{d}$  the rule definitions and  $f(\mathbf{x})$  is the specific problem that is solved.
